Sample Algorithm Questions with Answers

Question 1: Find the Largest Sum Subarray (Kadane's Algorithm)

Problem Statement: Given an array of integers, find the contiguous subarray with the maximum sum.

Approach:

- Use Kadane's algorithm for an efficient $O(n)$ solution.
- Keep track of current sum and maximum sum seen so far.

Answer:

```
```python
```

```
def max_subarray_sum(arr):
```

```
 max_current = max_global = arr[0]
```

```
 for num in arr[1:]:
```

```
 max_current = max(num, max_current + num)
```

```
 if max_current > max_global:
```

```
max_global = max_current
```

```
return max_global
```

```
...
```

Explanation:

- Initialize `max\_current` and `max\_global` with the first element.
- Traverse the array, updating `max\_current` as the maximum of current element or sum with previous.
- Update `max\_global` when a new maximum is found.
- Time complexity:  $O(n)$ , Space complexity:  $O(1)$ .

## Question 2: Implement Binary Search

Problem Statement: Given a sorted array, find the index of a target element using binary search.

Approach:

- Use divide-and-conquer by repeatedly halving the search space.

Answer:

```
```python
```

```
def binary_search(arr, target):
```

```
    low, high = 0, len(arr) - 1
```

```
    while low
```

```
        mid = (low + high) // 2
```

```
        if arr[mid] == target:
```

```
            return mid
```

```
        elif arr[mid]
```

```
            low = mid + 1
```

else:

high = mid - 1

return -1 Target not found

...

Explanation:

- Search space is narrowed by comparing the middle element with the target.
- Continues until the element is found or search space is exhausted.
- Time complexity: $O(\log n)$.

Question 3: Longest Common Subsequence (LCS)

Problem Statement: Find the length of the longest subsequence common to two strings.

Approach:

- Use dynamic programming to build a table of solutions for substrings.

Answer:

```
```python
```

```
def lcs_length(str1, str2):
```

```
 m, n = len(str1), len(str2)
```

```
 dp = [[0] * (n + 1) for _ in range(m + 1)]
```

```
 for i in range(1, m + 1):
```

```
 for j in range(1, n + 1):
```

```
 if str1[i - 1] == str2[j - 1]:
```

```
 dp[i][j] = dp[i - 1][j - 1] + 1
```

else:

$dp[i][j] = \max(dp[i - 1][j], dp[i][j - 1])$

return dp[m][n]

```

Explanation:

- `dp[i][j]` stores the length of LCS for substrings `str1[:i]` and `str2[:j]`.
- The table is filled iteratively based on character matches.
- Time complexity: $O(m \cdot n)$.

Question 4: Detecting Cycles in a Graph

Problem Statement: Given a directed graph, determine if it contains any cycle.

Approach:

- Use Depth-First Search (DFS).
- Maintain recursion stack to detect back edges indicating a cycle.

Answer:

```python

def has\_cycle(graph):

visited = set()

rec\_stack = set()

def dfs(node):

visited.add(node)

rec\_stack.add(node)

```
for neighbor in graph[node]:
```

```
 if neighbor not in visited:
```

```
 if dfs(neighbor):
```

```
 return True
```

```
 elif neighbor in rec_stack:
```

```
 return True
```

```
 rec_stack.remove(node)
```

```
 return False
```

```
for node in graph:
```

```
 if node not in visited:
```

```
 if dfs(node):
```

```
 return True
```

```
 return False
```

```
...
```

Explanation:

- `visited` tracks visited nodes.
- `rec\_stack` tracks nodes in the current recursion path.
- If a neighbor is in `rec\_stack`, a cycle exists.
- Time complexity:  $O(V + E)$ .

## Sample Algorithm Questions with Detailed Answers

### Question 1: Implement Binary Search and Analyze Its Time Complexity

Problem Statement:

Given a sorted array of integers, write an algorithm to find a target value efficiently.

Solution Approach:

Binary Search halves the search space at each step, making it highly efficient for sorted data.

Implementation:

```
```python

def binary_search(arr, target):

    left, right = 0, len(arr) - 1

    while left <= right:
        mid = left + (right - left) // 2

        if arr[mid] == target:
            return mid

        elif arr[mid] < target:
            left = mid + 1

        else:
            right = mid - 1

    return -1 Target not found
```

...

Analysis:

- Time Complexity: $O(\log n)$, where n is the number of elements.
- Space Complexity: $O(1)$, as it uses constant space.

Key Points:

- Works only on sorted data.
- Efficient for large datasets compared to linear search.

Question 2: Design an Algorithm to Find the Longest Increasing Subsequence (LIS)

Problem Statement:

Given an array of integers, find the length of the longest strictly increasing subsequence.

Approach:

Use Dynamic Programming with a time complexity of $O(n^2)$, or optimize with patience sorting to achieve $O(n \log n)$.

Naive DP Implementation ($O(n^2)$):

```
```python
```

```
def length_of_LIS(nums):
```

```
 if not nums:
```

```
 return 0
```

```
 dp = [1] * len(nums)
```

```
 for i in range(1, len(nums)):
```

```
 for j in range(i):
```

```
if nums[i] > nums[j]:
```

```
 dp[i] = max(dp[i], dp[j] + 1)
```

```
return max(dp)
```

```
...
```

Optimized Approach ( $O(n \log n)$ ):

```
```python
```

```
import bisect
```

```
def length_of_LIS(nums):
```

```
    sub = []
```

```
    for num in nums:
```

```
        idx = bisect.bisect_left(sub, num)
```

```
        if idx == len(sub):
```

```
            sub.append(num)
```

```
        else:
```

```
            sub[idx] = num
```

```
    return len(sub)
```

```
...
```

Analysis:

- Time Complexity: $O(n^2)$ for naive DP; $O(n \log n)$ for optimized.
- Space Complexity: $O(n)$.

Key Points:

- The key challenge is maintaining an array that tracks potential sequences.
- The $O(n \log n)$ approach uses binary search to efficiently update the subsequence.

Question 3: Design an Algorithm for the Knapsack Problem (Fractional)

Problem Statement:

Given weights and values of items, determine the maximum value obtainable in a knapsack of capacity W , where items can be broken into smaller parts.

Approach:

Use a greedy algorithm based on value-to-weight ratio.

Implementation:

```
```python
def fractional_knapsack(weights, values, capacity):
 items = sorted(zip(weights, values), key=lambda x: x[1]/x[0], reverse=True)
 total_value = 0
 for weight, value in items:
 if capacity == 0:
 break
 amount = min(weight, capacity)
 total_value += (amount / weight) * value
 capacity -= amount
 return total_value
```
```

Analysis:

- Time Complexity: $O(n \log n)$, due to sorting.
- Space Complexity: $O(n)$.

Key Points:

- Greedy strategy works optimally for fractional knapsack.
- For 0-1 knapsack, dynamic programming is required.
